

# SuperFlow: Loops

LESSON 05 · DESIGN &amp; CREATE

## What you'll learn

- Handle a whole batch in one SuperFlow run instead of rebuilding the same steps per item
- Start from a template (the Batch Sentiment Analyzer) rather than wiring a loop from scratch
- Use the loop node's two outputs — **loop** and **done** — for the right job
- Generalise one loop to resumes, support tickets, or spreadsheet rows without changing its shape

## Key concepts

**A lot of real work isn't one item — it's a whole batch, and you don't want to rebuild the steps for each one.** A stack of reviews, a folder of resumes, a list of orders: the answer is a loop. It's the one piece of SuperFlow the invoice lesson didn't cover, and it's what turns a single-run flow into a batch processor.

**Starting from a template beats building from scratch.** Begin a new SuperFlow, name it (here, *Northwind Review Sentiment*), and load the **Batch Sentiment Analyzer** template. It comes as a ready-made loop you can build on: a trigger, a code step that splits incoming text into a list (one item per line), the loop, an LLM classify step, and an output.

**A loop runs its inner steps once per item — that's the whole point.** Whatever list comes in, the loop sends each item through the steps inside it one at a time. Five reviews in means the classify step runs five times, independently, without you duplicating a single node.

**The loop node has two outputs, and the difference matters.** The **loop** output runs the inner steps once for every item on the list. The **done** output fires only once the loop has finished, and it carries the *full* set of results out the other side — so downstream steps see the complete batch as a single bundle, not a trickle of individual items.

**One loop generalises to any batch of the same shape.** Five customer reviews classified positive / negative / neutral with confidence scores is just one example — swap the reviews for resumes, support tickets, or rows in a spreadsheet and the same flow works unchanged. The loop is about the *shape* of the work, not the specific content.

## In Studio

Studio feature: **Create Agent → SuperFlow → loop node** (plus the template gallery).

1. Start a new **SuperFlow** and name it — *Northwind Review Sentiment*.

### TAKEAWAY

A lot of real work isn't one item — it's a whole batch, and you don't want to rebuild the steps for each one.

### TAKEAWAY

Starting from a template beats building from scratch.

### TAKEAWAY

A loop runs its inner steps once per item — that's the whole point.

### TAKEAWAY

The loop node has two outputs, and the difference matters.

### TAKEAWAY

One loop generalises to any batch of the same shape.

2. Instead of building from scratch, **start from a template**: the **Batch Sentiment Analyzer**. It loads a ready-made loop.
3. Read the shape: a **trigger** → a **code step** that splits incoming text into a list (one item per line) → the **loop** → an **LLM classify** step → an **output**.
4. Note the loop's two outputs: **loop** (runs the inner steps once per item) and **done** (fires once at the end, carrying the full result set).
5. **Run it** — paste five customer reviews, one per line, and hit **Run**. Watch each step light up as the loop sends the reviews through the classify step one at a time.
6. Read the result: five reviews in, five classifications out (positive / negative / neutral), each with a confidence score; the **done** branch hands back the whole set in a single bundle.
7. Generalise: swap the reviews for resumes, support tickets, or spreadsheet rows — the same loop handles them the same way.

## TRY THIS

- 1** Load the **Batch Sentiment Analyzer** template, paste in five short reviews (one per line), and run it. Confirm you get one classification per line, each with a confidence score.
- 2** Trace the loop's two outputs: follow what leaves the **loop** output versus what leaves the **done** output. Write one sentence on why a final report step should hang off **done**, not **loop**.
- 3** Repurpose the flow for a different batch — paste a handful of support tickets or resume blurbs instead of reviews, and adjust the classify step's prompt. *Notice you changed the content, not the loop.*
